Contents

1	The role of algorithms in computing (1-38)	2
1.1	Algorithms	2
1.1.1	Data structures	2
2	Getting started (39-49)	4
2.1	Insertion sort	4
	Loop invariant	4
2.2	Analyzing algorithms	5
	Execution cost evaluation method 1:Time cost of each statement	5

Chapter 1

The role of algorithms in computing (1-38)

Lecture 1: 1-27

Not relevant

19 Feb

Lecture 2: 27-54

1.1 Algorithms

21 Feb

1.1.1 Data structures

Definition 1.1.1 (Data structure). A way to store and organize data in order to facilitate access and modifications.

Definition 1.1.2 (Efficiency). Different algorithms solve the same problem but have different level of efficiency.

Example (Insertion sort vs merge sort). We note that the two sorting algorithms have different efficiency

Note (Insertion sort). $C_1 * n^2$ where C_1 is constant independent of n

Note (Merge sort). $C_2 * n * \log_2 n$ where C_2 is constant independent of n

Remark (Constant factor). insertion sort has a smaller constant factor than merge sort $C_1 < C_2$. The majority of the times constant factor has less influence than input size n

Definition 1.1.3 (Constant factor). Anything that doesn't depend on the input parameter(s)

Definition 1.1.4 (Input size). The input size can be the following:

- Number of items in the input, eg the number of items to sort
- Total number of bits, eg bitwise multiplication to multiply 2 integers
- Input size in term of 2 numbers, eg for finding the shortest path in a graph from a given source, usually the number of vertices plus the number of edges.

Chapter 2

Getting started (39-49)

2.1 Insertion sort

Definition 2.1.1 (keys). The numbers to be sorted. The input comes in the form of an array with " n " elements. The keys are often associated with other data, called "satellite data". Together they form a "record"

Definition 2.1.2 (Arrays). A data structure. A collection of items stored at contiguous memory locations. The idea is to store multiple items of the same type together. This makes it easier to calculate the position of each element by simply adding an offset to a base value, i.e., the memory location of the first element of the array (generally denoted by the name of the array).

Example (How it works). To sort an array of size N in ascending order iterate over the array and compare the current element (key) `keys` to its predecessor, if the key element is smaller than its predecessor, compare it to the elements before. Move the greater elements one position up to make space for the swapped element.

Algorithm 2.1: Insertion sort

```
1 for  $i \leftarrow 2$  to  $n$  do
2    $key = A[1]$  ;                               // Assign variable "key" to the index "i" of array "A"
3    $j = i - 1$  ;                                 // Insert  $A[1]$  into the sorted sub-array  $A[1 : i - 1]$ 
4   /* Conditional check while true                                     */
5   while  $j > 0$  and  $A[j] > key$  do
6      $A[j + 1] = A[j]$  ;           // Retrieve value at index "j" and assign this value to the element at
7     index  $j + 1$ 
8      $j = j - 1$ 
9   ;                                     // Swap  $j$  with the value at index  $j - 1$ 
10   $A[j + 1] = key$ 
```

Loop invariant

Definition. Loop invariant

Definition 2.1.3 (Loop invariant). A loop invariant is a condition (among program variables) that is necessarily true immediately before and immediately after each iteration of a loop.

Note (Boolean state thorough the iteration). Note that this says nothing about its truth or falsity part way through an iteration.

2.2 Analyzing algorithms

Definition 2.2.1 (Running time). Number of instruction and data accesses executed

Note (running time). The running time is dependent on various factor, such as [input size](#), current status^a, machine hardware.

However you can evaluate a formula depending on the input size, which is a general explanation of the time complexity

^aHow many keys are already sorted

Execution cost evaluation method 1:Time cost of each statement

Note (Statement execution number). "For" and "while" statements are executed one time more than the loop body. This is because the statement stop after the loop result in being false, which require an additional step.^a

^ato actually check if it "false"
